

Task B. Essay

What is a web page and how does a browser display HTML code? A web page is a text document written in HTML (HyperText Markup Language). HTML defines the structure and meaning of the content, acting as the “skeleton” of our website. When a user opens a web page, the browser reads the HTML file from top to bottom. First, it reads the `<head>` section to obtain meta-information such as the character set and the page title. Then it reads the `<body>` section to find the visible content. As the tags are read, the browser builds a DOM tree (document object model). When the browser sees the `<h1>` tag, it understands that this is the main heading, and when it sees the `<table>` tag, it builds a grid with the data. Since our project uses only HTML without CSS and JavaScript, the browser applies built-in styles (User-Agent Stylesheet). Therefore, our links are automatically blue and underlined, and the headings are bold. In our code, there are three places where, according to the task requirements, we used a semantic tag instead of `<div>`.

What technically happens when the user clicks the “Submit” button? First, in our `order.html` file, the form has the attributes `action="#"` and `method="POST"`. When the user clicks the “Submit” button, the browser collects all the data entered in the `<input>` fields. Since the action attribute is set to `#` (an empty anchor), the browser attempts to send a POST request to the same page. Because we don’t have a backend or a working server to process this request, the page simply reloads, the form clears all the data it contained, and at the end of the URL in the address bar, the `#` symbol appears. The data isn’t saved anywhere, and essentially the system works in a purely local manner — this is how the browser appears to be working when reading our page.
